

1 INTRODUCTION

This case study provides an example where local ecological knowledge (LEK) data were acquired and managed appropriately to provide insight into events that affect land-use planning.

The Pinedale gas field (PGF) is a major gas field in western Wyoming. The PGF was discovered in 1955 and produces 568 billion cubic feet of natural gas per year (U.S. Energy Information Administration 2015). The PGF ranks eighth in the United States for natural gas production.

Past natural disasters, such as an anthrax outbreak, can have an adverse effect on production from the field and also pose a local health risk if the burial site or sites are disturbed. This case study shows how local ecological knowledge helped avoid potential exposure to anthrax when drilling new oil and gas wells in a location where anthrax-infected animals were buried.

2 BACKGROUND

Anthrax is a spore from the bacterium *Bacillus anthracis*. These spores can persist in the environment for up to 50 years in the soil and up to 200 years in the bones of animals that have died from anthrax (Skirrow 2019). This persistence of anthrax spores in the environment presents a natural-disaster risk to agriculture and local economies. For example, the U.S. Department of Agriculture, Farm Service Agency (USDA-FSA) states that a ranch can receive up to 75% of the fair market value of any animal lost due to a natural disaster (USDA-FSA 2021). To put it another way, a rancher stands to lose 25% of their expected profits following a natural disaster if they are eligible at all given that natural disaster relief is not available if the adjusted gross income is greater than \$900,000.

In this context, any LEK that the landowners/ranchers can gather on known or suspected hazards, such as a burial area of anthrax-infected animals, will help to limit the health and economic risks to their operation and livelihood.

3 TRADITIONAL ECOLOGICAL KNOWLEDGE INPUT

In August 2008 one of the gas companies operating in the PGF started staking locations to drill new wells. A concerned rancher with historic knowledge of the Pinedale area contacted the Wyoming Department of Environmental Quality (WYDEQ) to share that the company had staked two wells on anthrax burial sites from an outbreak in the 1950s. The rancher sent the WYDEQ the coordinates of the burial sites.

Using the information from the rancher, the WYDEQ used mapping software in a geographic information system to plot the points with both 100- and 200-meter buffers, added the State Engineers Office permitted wells in the area (also buffered by 200 meters), and added the streams to the map to show the water downstream from the burial sites. Figure 1, which was the result of this effort, shows the water wells and oil and gas wells in proximity to the two anthrax burial locations.

4 END PRODUCT

The map of the anthrax burial sites was exported, and the jpg file was sent to the Wyoming Department of Agriculture (WDA). The WDA then worked to have the areas fenced off and posted signs that any work in the given areas had to get prior approval from the WDA. The results of this project will help prevent anthrax from contaminating the downstream water supply that people count on for drinking water, watering livestock, and irrigating fields.
